GENE TRANSFER FOR TREATING A CONNECTIVE TISSUE
OF A MAMMALIAN HOST

CROSS-REFERENCE TO RELATED APPLICATION

This is a continuation-in-part application of United States Application Serial No. 07/630,981, filed December 20, 1990, now pending.

10
BACKGROUND OF THE INVENTION

Field Of The Invention

15
The present invention relates to a method of introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for use in treating the mammalian host. This method discloses employing DNA vector molecules containing a gene encoding the product and infecting the connective tissue cells of the mammalian host using the DNA vector molecule. This invention provides a method of introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for use in treating the mammalian host including employing non-viral means for effecting such introduction.

20
The present invention also relates to a method to produce an animal model for the study of connective tissue pathology.

25
The present invention further relates to a method of using a gene encoding a truncated interleukin-1 receptor to resist the deleterious pathological changes associated with arthritis. More specifically, this invention provides a method wherein a gene coding for an extracellular interleukin-1 binding domain of an interleukin-1 receptor is introduced into synovial cells of a mammalian host in vivo for neutralizing the destructive activity of interleukin-1 upon cartilage and other soft tissues. As an alternative, the patients own synovial cells are transduced in vitro and

30
35

- 2 -

introduced back into the affected joint, using transplantation procedures such as for example, intra-articular injection.

5 As an alternative to the in vitro manipulation of synovia, the gene encoding the product of interest is introduced into liposomes and injected directly into the area of the joint, where the liposomes fuse with synovial cells, resulting in an in vivo gene transfer to synovial tissue. As an additional alternative to the in vitro manipulation of synovia, the gene encoding the product of interest is
10 introduced into the area of the joint as naked DNA. The naked DNA enters the synovial cell, resulting in an in vivo gene transfer to synovial tissue.

As an another alternative, hematopoietic progenitor cells or the mature lymphoid or myeloid cells may be transfected
15 in vitro, recovered and injected into the bone marrow of the patient using techniques known to the skilled artisan.

Brief Description Of The Related Art

Arthritis involves inflammation of a joint that is usually accompanied by pain and frequently changes in structure. Arthritis may result from or be associated with a
20 number of conditions including infection, immunological disturbances, trauma and degenerative joint diseases such as, for example, osteoarthritis. The biochemistry of cartilage degradation in joints and cellular changes have received
25 considerable investigation.

In a healthy joint, cells in cartilage (chondrocytes) and the surrounding synovium (synoviocytes) are in a resting state. In this resting state, these cells secrete basal levels of prostaglandin E_2 and various neutral
30 proteinases, such as, for example, collagenase, gelatinase and stromelysin, with the ability to degrade cartilage. During the development of an arthritic condition, these cells become activated. In the activated state, synoviocytes and

- 3 -

chondrocytes synthesize and secrete large amounts of prostaglandin E₂ and neutral proteinases.

In efforts to identify pathophysiologically relevant cell activators, it has been known that the cytokine interleukin-1 activates chondrocytes and synoviocytes and induces cartilage breakdown in vitro and in vivo. Additionally, interleukin-1 is a growth factor for synoviocytes and promotes their synthesis of matrix, two properties suggesting the involvement of interleukin-1 in the synovial hypertrophy that accompanies arthritis. In contrast, interleukin-1 inhibits cartilaginous matrix synthesis by chondrocytes, thereby suppressing repair of cartilage. Interleukin-1 also induces bone resorption and thus may account for the loss of bone density seen in rheumatoid arthritis. Interleukin-1 is inflammatory, serves as a growth factor for lymphocytes, is a chemotactic factor and a possible activator of polymorphonuclear leukocytes (PMNs). When present in a sufficient concentration, interleukin-1 may cause fever, muscle wasting and sleepiness.

The major source of interleukin-1 in the joint is the synovium. Interleukin-1 is secreted by the resident synoviocytes, which are joined under inflammatory conditions by macrophages and other white blood cells.

Much attention has been devoted to the development of a class of agents identified as the "Non-Steroidal Anti-Inflammatory Drugs" (hereinafter "NSAIDs"). The NSAIDs inhibit cartilage synthesis and repair and control inflammation. The mechanism of action of the NSAIDs appears to be associated principally with the inhibition of prostaglandin synthesis in body tissues. Most of this development has involved the synthesis of better inhibitors of cyclo-oxygenase, a key enzyme that catalyzes the formation of prostaglandin precursors (endoperoxides) from arachidonic acid. The anti-inflammatory effect of the NSAIDs is thought

- 4 -

to be due in part to inhibition of prostaglandin synthesis and release during inflammation. Prostaglandins are also believed to play a role in modulating the rate and extent of leukocyte infiltration during inflammation. The NSAIDs include, such as, for example, acetylsalicylic acid (aspirin), fenoprofen calcium (Nalfon® Pulvules®, Dista Products Company), ibuprofen (Motrin®, The Upjohn Company), and indomethacin (Indocin®, Merck, Sharp & Dohme).

In contrast, the studies upon which the present invention is based show that production of the various neutral proteinases with the ability to degrade cartilage occurs even if prostaglandin synthesis is completely blocked.

Therapeutic intervention in arthritis is hindered by the inability to target drugs, such as the NSAIDs, to specific areas within a mammalian host, such as, for example a joint. Traditional routes of drug delivery, such as for example, oral, intravenous or intramuscular administration, depend upon vascular perfusion of the synovium to carry the drug to the joint. This is inefficient because transynovial transfer of small molecules from the synovial capillaries to the joint space occurs generally by passive diffusion. This diffusion is less efficient with increased size of the target molecule. Thus, the access of large drug molecules, for example, proteins, to the joint space is substantially restricted. Intra-articular injection of drugs circumvents those limitations; however, the half-life of drugs administered intra-articularly is generally short. Another disadvantage of intra-articular injection of drugs is that frequent repeated injections are necessary to obtain acceptable drug levels at the joint spaces for treating a chronic condition such as, for example, arthritis. Because therapeutic agents heretofore could not be selectively targeted to joints, it was necessary to expose the mammalian host to systemically high concentrations of drugs in order to achieve a sustained,

- 5 -

intra-articular therapeutic dose. Exposure of non-target organs in this manner exacerbated the tendency of anti-arthritis drugs to produce serious side effects, such as for example, gastrointestinal upset and changes in the hematological, cardiovascular, hepatic and renal systems of the mammalian host.

It has been shown that genetic material can be introduced into mammalian cells by chemical or biologic means. Moreover, the introduced genetic material can be expressed so that high levels of a specific protein can be synthesized by the host cell. Cells retaining the introduced genetic material may include an antibiotic resistance gene thus providing a selectable marker for preferential growth of the transduced cell in the presence of the corresponding antibiotic. Chemical compounds for inhibiting the production of interleukin-1 are also known.

U.S. Patent No. 4,778,806 discloses a method of inhibiting the production of interleukin-1 by monocytes and/or macrophages in a human by administering through the parenteral route a 2-2'-[1,3-propan-2-onediyl-bis (thio)] bis-1 H-imidazole or a pharmaceutically acceptable salt thereof. This patent discloses a chemical compound for inhibiting the production of interleukin-1. By contrast, in one embodiment of the present invention, gene therapy is employed that is capable of binding to and neutralizing interleukin-1.

U.S. Patent No. 4,780,470 discloses a method of inhibiting the production of interleukin-1 by monocytes in a human by administering a 4,5-diaryl-2 (substituted) imidazole. This patent also discloses a chemical compound for inhibiting the production of interleukin-1.

U.S. Patent No. 4,794,114 discloses a method of inhibiting the 5-lipoxygenase pathway in a human by administering a diaryl-substituted imidazole fused to a thiazole, pyrrolidine or piperidine ring or a pharmaceutically

- 6 -

acceptable salt thereof. This patent also discloses a chemical compound for inhibiting the production of interleukin-1.

5 U.S. Patent No. 4,870,101 discloses a method for inhibiting the release of interleukin-1 and for alleviating interleukin-1 mediated conditions by administering an effective amount of a pharmaceutically acceptable anti-oxidant compound such as disulfiram, tetrakis [3-(2,6-di-tert-butyl-4-hydroxyphenyl) propionyloxy methyl] methane or 2,4-di-
10 isobutyl-6-(N,N-dimethylamino methyl)-phenol. This patent discloses a chemical compound for inhibiting the release of interleukin-1.

U.S. Patent No. 4,816,436 discloses a process for the use of interleukin-1 as an anti-arthritic agent. This
15 patent states that interleukin-1, in association with a pharmaceutical carrier, may be administered by intra-articular injection for the treatment of arthritis or inflammation. In contrast, the present invention discloses a method of using and preparing a gene that is capable of binding to and
20 neutralizing interleukin-1 as a method of resisting arthritis.

U.S. Patent No. 4,935,343 discloses an immunoassay method for the detection of interleukin-1 beta that employs a
25 monoclonal antibody that binds to interleukin-1 beta but does not bind to interleukin-1 beta. This patent discloses that the monoclonal antibody binds to interleukin-1 beta and blocks the binding of interleukin-1 beta to interleukin-1 receptors, and thus blocking the biological activity of interleukin-1 beta. The monoclonal antibody disclosed in this patent may
30 be obtained by production of an immunogen through genetic engineering using recombinant DNA technology. The immunogen is injected into a mouse and thereafter spleen cells of the mouse are immortalized by fusing the spleen cells with myeloma cells. The resulting cells include the hybrid continuous cell lines (hybridomas) that may be later screened for monoclonal

- 7 -

antibodies. This patent states that the monoclonal antibodies of the invention may be used therapeutically, such as for example, in the immunization of a patient, or the monoclonal antibodies may be bound to a toxin to form an immunotoxin or to a radioactive material or drug to form a radio pharmaceutical or pharmaceutical.

U.S. Patent No. 4,766,069 discloses a recombinant DNA cloning vehicle having a DNA sequence comprising the human interleukin-1 gene DNA sequence. This patent provides a process for preparing human interleukin-1 beta, and recovering the human interleukin-1 beta. This patent discloses use of interleukin-1 as an immunological reagent in humans because of its ability to stimulate T-cells and B-cells and increase immunoglobulin synthesis.

U.S. Patent No. 4,396,601 discloses a method for providing mammalian hosts with additional genetic capability. This patent provides that host cells capable of regeneration are removed from the host and treated with genetic material including at least one marker which allows for selective advantage for the host cells in which the genetic material is capable of expression and replication. This patent states that the modified host cells are then returned to the host under regenerative conditions. In the present invention, genetic material may be directly introduced (a) into host cells in vivo or (b) into synoviocytes in vitro for subsequent transplantation back into the patient's joints.

U.S. Patent No. 4,968,607 discloses a DNA sequence encoding a mammalian interleukin-1 receptor protein which exhibits interleukin-1 binding activity.

In spite of these prior art disclosures, there remains a very real and substantial need for a method of introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host in vitro, or alternatively in vivo, for use in treating the mammalian

- 8 -

host. Further, there is a need for a process wherein a gene encoding a truncated interleukin-1 receptor is used to resist the deleterious pathological changes associated with arthritis. More specifically there is a need for such a process where a gene coding for the extracellular interleukin-1 binding domain of the interleukin-1 receptor, capable of binding to and neutralizing interleukin-1 is expressed in host synovial cells in vivo.

SUMMARY OF THE INVENTION

The present invention has met the hereinbefore described need. A method of introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for use in treating the mammalian host is provided for in the present invention. This method includes employing recombinant techniques to produce a DNA vector molecule containing the gene encoding for the product and infecting the connective tissue cell of the mammalian host using the DNA vector molecule containing the gene coding for the product. The DNA vector molecule can be any DNA molecule capable of being delivered and maintained within the target cell or tissue such that the gene encoding the product of interest can be stably expressed. The DNA vector molecule preferably utilized in the present invention is either a viral DNA vector molecule or a plasmid DNA viral molecule. This method preferably includes introducing the gene encoding the product into the cell of the mammalian connective tissue for a therapeutic use.

More specifically, this method includes employing as the gene a gene capable of encoding at least one of the materials which is selected from the group which includes (a) a human interleukin-1 receptor antagonist protein or a biologically active derivative or fragment thereof, (b) a Lac Z marker gene capable of encoding a beta-galactosidase protein or a biologically active derivative or fragment

- 9 -

thereof, (c) a soluble interleukin-1 receptor protein or a biologically active derivative or fragment thereof, (d) a proteinase inhibitor, and (e) a cytokine, and employing as the viral vector at least one vector which is selected from the group which includes (a) a retroviral vector including at least one of the materials selected from the group which includes MFG and BAG, (b) an adeno-associated virus, (c) an adenovirus, and (d) a herpes virus, including but not limited to herpes simplex 1 or herpes simplex 2.

A further embodiment of the present invention includes employing as the gene a gene capable of encoding at least one of the materials which is selected from the group which includes (a) a human interleukin-1 receptor antagonist protein or a biologically active derivative or fragment thereof, (b) a Lac Z marker gene capable of encoding a beta-galactosidase protein or a biologically active derivative or fragment thereof, (c) a soluble interleukin-1 receptor protein or a biologically active derivative or fragment thereof, (d) a proteinase inhibitor, and (e) a cytokine, and employing as the DNA plasmid vector any DNA plasmid vector known to one of ordinary skill in the art capable of stable maintenance within the targeted cell or tissue upon delivery, regardless of the method of delivery utilized. One such method is the direct delivery of the DNA vector molecule, whether it be a viral or plasmid DNA vector molecule, to the target cell or tissue. This method also includes employing as the gene a gene capable of encoding at least one of the materials selected from the group which includes (a) a human interleukin-1 receptor antagonist protein or biologically active derivative or fragment thereof, (b) a Lac Z marker gene capable of encoding a beta-galactosidase protein or biologically active derivative or fragment thereof, (c) a soluble interleukin-1 receptor protein or biologically active derivative or fragment thereof, (d) a proteinase inhibitor and

- 10 -

(e) a cytokine. In a specific method disclosed as an example, and not as a limitation to the present invention, a DNA plasmid vector containing the interleukin-1 beta coding sequence was ligated downstream of the cytomegalovirus (CMV) promoter. This DNA plasmid construction was encapsulated within liposomes and injected intra-articularly into the knee joints of recipient rabbits. Interleukin-1 beta was expressed and significant amounts of interleukin-1 beta was recovered from the synovial tissue. An alternative is injection of the naked plasmid DNA into the knee joint, allowing direct transfection of the DNA into the synovial tissue.

Another embodiment of this invention provides a method for introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for use in treating the mammalian host. This method includes employing non-viral means for introducing the gene encoding for the product into the connective tissue cell. More specifically, this method includes employing non-viral means which is selected from at least one of the group which includes (a) at least one liposome, (b) $\text{Ca}_3(\text{PO}_4)_2$, (c) electroporation, and (d) DEAE-dextran, and includes employing as the gene a gene capable of encoding at least one of the materials selected from the group which includes (a) a human interleukin-1 receptor antagonist protein or biologically active derivative or fragment thereof, (b) a Lac Z marker gene capable of encoding a beta-galactosidase protein or biologically active derivative or fragment thereof, (c) a soluble interleukin-1 receptor protein or biologically active derivative or fragment thereof, (d) a proteinase inhibitor (e) a soluble tumor necrosis factor receptor protein or biologically active derivative or fragment thereof, and (f) a cytokine.

A further embodiment of this invention provides an additional method for introducing at least one gene encoding

- 11 -

a product into at least one cell of a connective tissue of a mammalian host for use in treating the mammalian host. This additional method includes employing the biologic means of utilizing a virus to deliver the DNA vector molecule to the target cell or tissue. Preferably, the virus is a psuedovirus, the genome having been altered such that the psuedovirus is capable only of delivery and stable maintenance within the target cell; but not retaining an ability to replicate within the target cell or tissue. The altered viral genome is further manipulated by recombinant DNA techniques such that the viral genome acts as a DNA vector molecule which contains the heterologous gene of interest to be expressed within the target cell or tissue. This method also includes employing as the gene a gene capable of encoding at least one of the materials selected from the group which includes (a) a human interleukin-1 receptor antagonist protein or biologically active derivative or fragment thereof, (b) a Lac Z marker gene capable of encoding a beta-galactosidase protein or biologically active derivative or fragment thereof, (c) a soluble interleukin-1 receptor protein or biologically active derivative or fragment thereof, (d) a proteinase inhibitor and (e) a cytokine.

A further embodiment of this invention includes a method to produce an animal model for the study of connective tissue pathology which includes introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host.

Another embodiment of this invention provides a method of using the gene encoding an extracellular interleukin-1 binding domain of the interleukin-1 receptor. This gene is capable of binding to and neutralizing interleukin-1 in vivo to substantially resist the degradation of cartilage in a mammalian host. Unlike previous pharmacological efforts, the method of this invention employs

- 12 -

gene therapy in vivo to address the chronic debilitating effects of arthritis.

5 A preferred method of using the gene coding for the truncated interleukin-1 receptor of this invention involves employing recombinant techniques to generate a cell line which produces infectious retroviral particles containing the gene coding for the truncated interleukin-1 receptor. The producer cell line is generated by inserting the gene coding into a retroviral vector under the regulation of a suitable eukaryotic promoter, transfecting the retroviral vector containing the gene coding into the retroviral packaging cell line for the production of a viral particle that is capable of expressing the gene coding for the truncated interleukin-1 receptor, and infecting the synovial cells of a mammalian host using the viral particle.

15 More specifically, the method of using the hereinbefore described gene coding for the truncated interleukin-1 receptor involves introducing the viral particles obtained from the retroviral packaging cell line directly by intra-articular injection into a joint space of a mammalian host that is lined with synovial cells. In a preferred embodiment, synoviocytes recovered from the knee joint are cultured in vitro for subsequent utilization as a delivery system for gene therapy. It will be apparent that Applicants are not limited to the use of the specific synovial tissue disclosed. It would be possible to utilize other tissue sources, such as skin cells, for in vitro culture techniques. The method of using the gene of this invention may be employed both prophylactically and in the therapeutic treatment of arthritis. It will also be apparent that Applicants are not limited to prophylactic or therapeutic applications in treating only the knee joint. It would be possible to utilize the present invention either

- 13 -

prophylactically or therapeutically to treat arthritis in any susceptible joint.

5 In another embodiment of this invention, a method of using the hereinbefore described gene coding for the truncated interleukin-1 receptor involves infecting synovial cells in culture with the viral particles and subsequently transplanting the infected synovial cells back into the joint. This method of using the gene of this invention may also be employed prophylactically and in the therapeutic treatment of
10 arthritis in any area susceptible to the disorder.

In another embodiment of this invention, a method of using the gene coding for an extracellular interleukin-1 binding domain of the interleukin-1 receptor that is capable of binding to and neutralizing interleukin-1 includes
15 employing recombinant techniques to produce a retrovirus vector carrying two genes. The first gene encodes the extracellular interleukin-1 binding domain of the interleukin receptor, and the second gene encodes for selectable antibiotic resistance. This method of use involves
20 transfecting the retrovirus vector into a retrovirus packaging cell line to obtain a cell line producing infectious retroviral particles carrying the gene.

Another embodiment of this invention provides a method of preparing a gene encoding an extracellular
25 interleukin-1 binding domain of the interleukin-1 receptor including synthesizing the gene by a polymerase chain reaction, introducing the amplified interleukin-1 receptor coding sequence into a retroviral vector, transfecting the retroviral vector into a retrovirus packaging cell line and
30 collecting viral particles from the retrovirus packaging cell line.

In another embodiment of this invention, a compound for parenteral administration to a patient in a therapeutically effective amount is provided for that contains

- 14 -

a gene encoding an extracellular interleukin-1 binding domain of the interleukin-1 receptor and a suitable pharmaceutical carrier.

5 Another embodiment of this invention provides for a compound for parenteral administration to a patient in a prophylactically effective amount that includes a gene encoding an extracellular interleukin-1 binding domain of the interleukin-1 receptor and a suitable pharmaceutical carrier.

10 An additional embodiment of the invention involves transfection of hematopoietic progenitor cells or mature lymphoid or myeloid cells with a DNA vector molecule containing any of the gene or genes disclosed throughout the specification. The transfected cells are recovered and injected into the bone marrow of the patient using techniques
15 known and available to one of ordinary skill in the art. It will be possible, within the scope of this method, to use cells derived from donor bone marrow instead of cells derived from recipient bone marrow so as to modify rejection.

20 In another embodiment of the invention, synoviocytes are transfected in vivo subsequent to direct intra-articular injection of a DNA molecule containing the gene of interest into the joint. Transfection of the recipient synovial cells bypasses the requirement of removal, culturing, in vitro transfection, selection and transplanting the DNA vector
25 containing - synoviocytes (as disclosed in the Example section) to promote stable expression of the heterologous gene of interest. Methods of injecting the DNA molecule into the joint includes, but is not limited to, encapsulation of the DNA molecule into cationic liposomes or the direct injection
30 of the DNA molecule itself into the joint. The DNA molecule, regardless of the form of presentation to the knee joint, is preferably presented as a DNA vector molecule, either as viral DNA vector molecule, or preferably, a DNA plasmid vector molecule. Expression of the heterologous gene of interest is

- 15 -

ensured by inserting a promoter fragment active in eukaryotic cells directly upstream of the coding region of the heterologous gene. One of ordinary skill in the art may utilize known strategies and techniques of vector construction to ensure appropriate levels of expression subsequent to entry of the DNA molecule into the synovial tissue.

It is an object of the present invention to provide a method of introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for use in treating the mammalian host.

It is an object of the invention to provide a method of introducing a gene encoding a product into at least one cell of a connective tissue of a mammalian host for a therapeutic use.

It is an object of the present invention to provide a method of introducing into the synovial lining cells of a mammalian arthritic joint at least one gene which codes for proteins having therapeutic properties.

It is an object of the present invention to provide an animal model for the study of connective tissue pathology.

It is an object of the present invention to provide a method of using in vivo a gene coding for the extracellular interleukin-1 binding domain of the interleukin-1 receptor that is capable of binding to and neutralizing substantially all isoforms of interleukin-1, including interleukin-1 alpha and interleukin-1 beta.

It is an object of the present invention to provide a method of using a gene in vivo in a mammalian host that is capable of binding to and neutralizing substantially all isoforms of interleukin-1 and thus, substantially resist the degradation of cartilage and protect surrounding soft tissues of the joint space.

It is an object of the present invention to provide a method of using in vivo a gene coding for the extracellular

- 16 -

interleukin-1 binding domain of the interleukin-1 receptor that is capable of binding to and neutralizing substantially all isoforms of interleukin-1 for the prevention of arthritis in patients that demonstrate a high susceptibility for developing the disease.

5 It is an object of the present invention to provide a method of using in vivo a gene coding for an extracellular interleukin-1 binding domain of an interleukin-1 receptor that is capable of binding to and neutralizing substantially all
10 isoforms of interleukin-1 for the treatment of patients with arthritis.

It is an object of the present invention to provide a method of using in vivo a gene or genes that address the chronic debilitating pathophysiology of arthritis.

15 It is a further object of the present invention to provide a compound for parenteral administration to a patient which comprises a gene encoding an extracellular interleukin-1 binding domain of the interleukin-1 receptor and a suitable pharmaceutical carrier.

20 These and other objects of the invention will be more fully understood from the following description of the invention, the referenced drawings attached hereto and the claims appended hereto.

BRIEF DESCRIPTION OF THE DRAWINGS

25 Figure 1 shows the structure of the cDNA encoding the human interleukin-1 receptor antagonist protein (IRAP) gene inserted into the NcoI and BamHI cloning sites of the retroviral vector MFG.

30 Figure 2 shows the structure of the cDNA encoding the human interleukin-1 receptor antagonist protein (IRAP) gene with a selectable neo marker inserted into the retroviral vector MFG.

Figure 3 shows a micrograph of synovium recovered from the knee of a rabbit approximately one month after

- 17 -

intra-articular injection of Lac Z⁺, neo synoviocytes employing the methods of this invention.

Figure 4 shows a Western blot demonstrating the production of interleukin-1 receptor antagonist protein by four cultures of HIG-82 cells (Georgescu 1988) infected using the method of this invention employing the MFG-IRAP viral vector.

Figure 5 shows data demonstrating the inhibition of chondrocytes by the addition of medium conditioned by MFG-IRAP infected HIG-82 cells.

Figure 6 shows the uptake and expression of the Lac Z gene by synoviocytes using lipofection. Well 1 - Control cells, treated with liposomes alone; Well 2 - Control cells, treated with DNA alone; Well 3 - DNA + 150 nmole liposomes; Well 4 - DNA + 240 nmole liposomes; Well 5 - DNA + 300 nmole liposomes; Well 6 - DNA + 600 nmole liposomes.

DETAILED DESCRIPTION OF THE INVENTION

As used herein, the term "patient" includes members of the animal kingdom including but not limited to human beings.

As used herein, the term "mammalian host" includes members of the animal kingdom including but not limited to human beings.

As used herein, the term "connective tissue" includes but is not limited to a ligament, a cartilage, a tendon, and a synovium of a mammalian host.

- 18 -

As used herein, the term "DC-chol" means a cationic liposome containing cationic cholesterol derivatives. The "DC-chol" molecule includes a tertiary amino group, a medium length spacer arm (two atoms) and a carbamoyl linker bond as described in Biochem. Biophys. Res. Commun., 179:280-285 (1991), X. Gao and L. Huang.

As used herein, "SF-chol" is defined as a type of cationic liposome.

As used herein, the term "biologically active" used in relation to liposomes denotes the ability to introduce functional DNA and/or proteins into the target cell.

As used herein, the term "biologically active" in reference to a nucleic acid, protein, protein fragment or derivative thereof is defined as an ability of the nucleic acid or amino acid sequence to mimic a known biological function elicited by the wild type form of the nucleic acid or protein.

As used herein, the term "maintenance", when used in the context of liposome delivery, denotes the ability of the introduced DNA to remain present in the cell. When used in other contexts, it means the ability of targeted DNA to remain present in the targeted cell or tissue so as to impart a therapeutic effect.

Connective tissues are difficult organs to target therapeutically. Intravenous and oral routes of drug delivery that are known in the art provide poor access to these connective tissues and have the disadvantage of exposing the mammalian host body systemically to the therapeutic agent. More specifically, known intra-articular injection of joints provides direct access to a joint. However, most of the injected drugs have a short intra-articular half-life. The present invention solves these problems by introducing into the connective tissue of a mammalian host genes encoding for proteins that may be used to treat the mammalian host. More

- 19 -

specifically, this invention provides a method for introducing into the connective tissue of a mammalian host genes encoding for proteins with anti-arthritic properties.

5 The present invention provides a method of introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for use in treating the mammalian host which comprises employing recombinant techniques to produce a viral vector which contains the gene encoding for the product, and infecting the
10 connective tissue cell of the mammalian host using the viral vector containing the gene coding for the product. This method preferably includes introducing the gene encoding the product into at least one cell of the connective tissue of the mammalian host for a therapeutic use.

15 In one embodiment of this invention, the method as hereinbefore described includes employing as the gene a gene capable of encoding a human interleukin-1 receptor antagonist protein (IRAP).

20 In another embodiment of this invention, the method as hereinbefore described includes employing as the gene a Lac Z marker gene capable of encoding a beta-galactosidase.

In another embodiment of this invention, the method as hereinbefore described includes employing as the gene a gene capable of encoding a soluble interleukin-1 receptor.

25 Another embodiment of this invention includes the method as hereinbefore described including employing as the gene a gene capable of encoding at least proteinase inhibitor. More specifically, this method preferably includes employing a tissue inhibitor of a metalloproteinases as the proteinase
30 inhibitor.

Another embodiment of this invention includes the method as hereinbefore described including employing as the gene a gene capable of encoding at least one cytokine. More specifically, this method includes employing as the cytokine

- 20 -

at least one material selected from the group consisting of interleukin-1 alpha, interleukin-1 beta, interleukin-2, interleukin-3, interleukin-4, interleukin-5, interleukin-6, interleukin-7, interleukin-8, interleukin-9, interleukin-10, interleukin-11, interleukin-12, tumor necrosis factor α , and tumor necrosis factor β .

A further embodiment of this invention includes a method as hereinbefore described including employing as the cytokine at least one transforming growth factor. More specifically, this method includes employing as the transforming growth factor a growth factor selected from the group consisting of TGF-beta₁, TGF-beta₂, TGF-beta₃, and TGF-alpha. Each transforming growth factor is commercially available from R & D Systems, 614 McKinley Place, N.E., Minneapolis, MN 55413.

In another embodiment of this invention, the method as hereinbefore described includes employing as the cytokine at least one fibroblast growth factor. The fibroblast growth factors are also commercially available from R & D Systems, 614 McKinley Place, N.E., Minneapolis, MN 55413.

Another embodiment of this invention includes the method as hereinbefore described including employing as the viral vector a retroviral vector. More specifically, this method includes employing as the retroviral vector at least one material selected from the group consisting of MFG and BAG. A preferred embodiment of this invention includes providing the method as hereinbefore described including employing as the gene a gene capable of encoding a human interleukin-1 receptor antagonist protein and employing MFG as the retroviral vector.

Another preferred embodiment of this invention includes the method as hereinbefore described including employing a Lac Z marker gene as the gene capable of encoding

- 21 -

a beta-galactosidase and employing MFG as the retroviral vector.

Another preferred embodiment of this invention provides the method as hereinbefore described including employing a Lac Z neo marker gene as the gene capable of encoding a beta-galactosidase and employing BAG as the retroviral vector.

In a most preferred embodiment of this invention, the method as hereinbefore described includes employing a retroviral vector selected from the group consisting of MFG and BAG and includes employing as the gene a gene capable of encoding a soluble interleukin-1 receptor.

In another embodiment of this invention, a method as hereinbefore described is provided including employing as the gene a gene capable of encoding at least one proteinase inhibitor and including employing as the retroviral vector at least one material selected from the group consisting of MFG and BAG.

In another embodiment of this invention, a method as hereinbefore described is provided which includes employing as the retroviral vector at least one material selected from the group consisting of MFG and BAG and including employing as the gene a gene capable of encoding at least one cytokine as hereinbefore described.

In another embodiment of this invention, a method is provided for introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for use in treating the mammalian host which comprises employing recombinant techniques to produce a viral vector which contains the gene encoding for the product and infecting the connective tissue cell of the mammalian host using the viral vector containing the gene coding for the product, wherein the viral vector is at least one vector selected from the group consisting of an adeno-associated virus, an

- 22 -

adenovirus, and a herpes virus, such as herpes simplex type-1 or herpes simplex type-2.

This method includes employing as the gene a gene capable of encoding at least one material selected from the group which includes (a) a human interleukin-1 receptor antagonist protein, (b) a soluble interleukin-1 receptor, (c) a Lac Z marker gene capable of encoding a beta-galactosidase, (d) at least one proteinase inhibitor and (e) at least one cytokine. More specifically, this method includes employing a tissue inhibitor of metalloproteinases as the proteinase inhibitor and includes employing as the cytokine at least one of the materials selected from the group which includes (a) at least one transforming growth factor selected from the group consisting of TGF-beta₁, TGF-beta₂, TGF-beta₃, and TGF-alpha, (b) at least one fibroblast growth factor, (c) interleukin-1 alpha, (d) interleukin-1 beta, (e) interleukin-2, (f) interleukin-3, (g) interleukin-4, (h) interleukin-5, (i) interleukin-6, (j) interleukin-7, (k) interleukin-8, (l) interleukin-9, (m) interleukin-10, (n) interleukin-11, and (o) interleukin-12 (p) tumor necrosis factor α , and (q) tumor necrosis factor β .

Another embodiment of this invention includes the method as hereinbefore described including introducing the gene into a connective tissue which tissue is selected from the group consisting of a ligament, a cartilage, a tendon, and a synovium. It is preferable that this method includes employing a cruciate ligament as the ligament. Most preferable this method includes employing as the cruciate ligament a ligament selected from the group consisting of an anterior cruciate ligament and a posterior cruciate ligament.

Another embodiment of this invention includes the method as hereinbefore described including employing as the gene a gene having DNA that is capable of maintenance and expression.

- 23 -

5 A further embodiment of this invention includes the method as hereinbefore described including introducing the gene into the cell in vitro. This method includes subsequently transplanting the infected cell into the mammalian host. This method also includes after effecting the infecting of the connective tissue cell but before the transplanting of the infected cell into the mammalian host, storing the infected connective tissue cell. It will be appreciated by those skilled in the art that the infected connective tissue cell may be stored frozen in 10 percent DMSO in liquid nitrogen. This method includes employing a method to substantially prevent the development of arthritis in a mammalian host having a high susceptibility of developing arthritis.

15 The method of this invention includes employing the method on an arthritic mammalian host for a therapeutic use. This method includes employing a method to repair and regenerate the connective tissue which tissue is selected from the group consisting of a ligament, a cartilage, a tendon, and a synovium. This method includes employing the method on a mammalian host that is a human being.

25 Another embodiment of this invention includes a method of introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for use in treating the mammalian host as hereinbefore described including effecting in vivo the infection of the cell by introducing the viral vector containing the gene coding for the product directly into the mammalian host. Preferably, this method includes effecting the direct introduction into the mammalian host by intra-articular injection. This method includes employing the method to substantially prevent a development of arthritis in a mammalian host having a high susceptibility of developing arthritis. This method also includes employing the method on

- 24 -

an arthritic mammalian host for therapeutic use. Further this method as includes employing the method to repair and regenerate the connective tissue as hereinbefore defined.

5 In yet another embodiment of this invention, a method of introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for use in treating the mammalian host includes employing non-viral means for introducing the gene encoding for the product into the connective tissue cell. This method includes
10 employing non-viral means selected from the group consisting of at least one liposome, $\text{Ca}_3(\text{PO}_4)_2$, electroporation, and DEAE-dextran. This method includes employing as the liposome a material selected from the group consisting of DC-chol and SF-chol.

15 It will be understood that the method of this invention of introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for use in treating the mammalian host that includes employing non-viral means for introducing the gene encoding
20 for the product into the connective tissue cell is a non-infectious delivery system. An advantage of the use of a non-infectious delivery system is the elimination of insertional mutagenesis and virally induced disease.

25 It will be appreciated by those skilled in the art, that the viral vectors employing a liposome are not limited by cell division as is required for the retroviruses to effect infection and integration of connective tissue cells. This method employing non-viral means as hereinbefore described includes employing as the gene a gene capable of encoding at
30 least one of the following materials selected from the group which includes (a) a human interleukin-1 receptor antagonist protein, (b) a Lac Z marker gene capable of encoding a beta-galactosidase, (c) a soluble interleukin-1 receptor, (d) at least one proteinase inhibitor, (e) at least one

- 25 -

transforming growth factor, and (f) at least one cytokine. More specifically, this method includes employing as the cytokine a cytokine selected from the group which includes interleukin-1 alpha, interleukin-1 beta, interleukin-2, interleukin-3, interleukin-4, interleukin-5, interleukin-6, interleukin-7, interleukin-8, interleukin-9, interleukin-10, interleukin-11, interleukin-12, tumor necrosis factor α , tumor necrosis factor β , at least one fibroblast growth factor, and at least one transforming growth factor. Preferably, this method includes employing as the transforming growth factor a growth factor selected from the group consisting of TGF-beta₁, TGF-beta₂, TGF-beta₃, and TGF-alpha.

Another preferred embodiment of this invention includes providing the method employing non-viral means as hereinbefore described which includes employing a tissue inhibitor of metalloproteinases as the proteinase inhibitor. This method employing non-viral means for introducing the gene encoding for the product into the connective tissue cell as hereinbefore described includes introducing the gene into the connective tissue which tissue is selected from the group consisting of a ligament, a cartilage, a tendon, and a synovium. Preferably, this method includes employing a cruciate ligament as the ligament. The cruciate ligament is selected from the group consisting of an anterior cruciate ligament and an posterior cruciate ligament.

Another embodiment of this invention provides the method of introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for use in treating the mammalian host which includes employing non-viral means as hereinbefore described and includes employing as the gene a gene having DNA that is capable of maintenance and expression.

In yet a further embodiment of this invention, the method of introducing at least one gene encoding a product

- 26 -

into at least one cell of a connective tissue of a mammalian host for use in treating the mammalian host is provided that includes employing non-viral means for introducing the gene encoding for the product into the connective tissue cell in vitro and includes subsequently transplanting the cell having the gene into the mammalian host. Another embodiment of this invention provides a method including after introducing the gene encoding for the product in the connective tissue cell and before the transplanting of the connective tissue cell having the gene into the mammalian host, storing the connective tissue cell having the gene. This method includes storing connective tissue cell frozen in 10 percent DMSO in liquid nitrogen. This method includes employing a method to substantially prevent the development of arthritis in a mammalian host having a high susceptibility of developing arthritis. Further, this method includes employing the method on an arthritic mammalian host for a therapeutic use. This method includes employing the method to repair and regenerate the connective tissue which tissue is selected from the group consisting of a ligament, a cartilage, a tendon, and a synovium.

A further embodiment of this invention provides a method of introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for use in treating the mammalian host which includes employing non-viral means in vivo for directly introducing the gene encoding for the product into the connective tissue cell of the mammalian host. The non-viral means is selected from the group consisting of at least one liposome, $\text{Ca}_3(\text{PO}_4)_2$, and DEAE-dextran. Preferably, this method includes effecting the in vivo introduction into the mammalian host by intra-articular injection. This method includes employing the method to substantially prevent the development of arthritis in a mammalian host having a high susceptibility of developing

- 27 -

arthritis. Further, this method includes employing the method on an arthritic mammalian host for a therapeutic use. This method also includes employing the method to repair and regenerate the connective tissue which tissue is selected from the group consisting of a ligament, a cartilage, a tendon, and a synovium.

Another embodiment of the present invention is a method to produce an animal model for the study of connective tissue pathology. As will be understood by those skilled in the art, over-expression of interleukin-1 in the joint of a mammalian host is generally responsible for the induction of an arthritic condition. This invention provides a method for producing an animal model using the hereinbefore described gene transfer technology of this invention. Preferably, the method of this invention provides a method for producing an animal model using the hereinbefore described gene transfer technology of this invention to effect an animal model for arthritis. For example, constitutive expression of interleukin-1 in the joint of a rabbit following the method of gene transfer provided for by this invention leads to the onset of an arthritic condition. It will be appreciated by those skilled in the art that this rabbit model is suitable for use for the testing of therapeutic agents. This method includes introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host comprising (a) employing recombinant techniques to produce a viral vector which contains the gene encoding for the product and (b) infecting the connective tissue cell of the mammalian host using the viral vector containing the gene coding for the product for effecting the animal model. This method includes employing as the gene a material selected from the group consisting of a cytokine and a proteinase. This method includes employing as the cytokine a material selected from the group consisting of interleukin-1 alpha,

- 28 -

interleukin-1 beta, and tumor necrosis factor- α (TNF- α). This method includes employing as the proteinase a matrix metalloproteinase. The matrix metalloproteinase is an enzyme selected from the group consisting of a collagenase, a gelatinase and a stromelysin. It will be apparent that use of the term "a collagenase, a gelatinase and a stromelysin" is meant to include the plural, and not be limited to the singular. It is well known in the art that numerous collagenases, gelatinases and stromelysins could be employed as a matrix metalloproteinase in the present invention. A further embodiment of this invention provides a method to produce an animal model for the study of connective tissue pathology which includes employing non-viral means for introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for effecting the animal model. The non-viral means is selected from the group consisting of at least one liposome, $\text{Ca}_3(\text{PO}_4)_2$, electroporation, and DEAE-dextran. This method includes employing as the gene a material selected from the group consisting of a cytokine and a proteinase. This method includes employing as the cytokine a material selected from the group consisting of interleukin-1 alpha, interleukin-1 beta, and TNF- α . This method also includes employing as the proteinase a matrix metalloproteinase. The matrix metalloproteinase includes an enzyme selected from at least one of the group consisting of a collagenase, a gelatinase, and a stromelysin.

A further embodiment of the present invention includes employing as the gene a gene capable of encoding at least one of the materials which is selected from the group which includes (a) a human interleukin-1 receptor antagonist protein or a biologically active derivative or fragment thereof, (b) a Lac Z marker gene capable of encoding a beta-galactosidase protein or a biologically active derivative

- 29 -

or fragment thereof, (c) a soluble interleukin-1 receptor protein or a biologically active derivative or fragment thereof, (d) a proteinase inhibitor, (e) a soluble tumor necrosis factor receptor protein or a biologically active derivative or fragment thereof and (f) a cytokine, and employing as the DNA vector any DNA vector, preferably a plasmid or viral vector, known to one of ordinary skill in the art capable of stable maintenance within the targeted cell or tissue upon delivery, regardless of the method of delivery utilized. In one embodiment of the invention, synoviocytes are transfected in vivo subsequent to direct intra-articular injection of a DNA molecule containing the gene of interest into the joint. Transfection of the recipient synovial cells bypasses the requirement of removal, culturing, in vitro transfection, selection and transplanting the DNA vector containing - synoviocytes (as disclosed in the Example section) to promote stable expression of the heterologous gene of interest. Methods of injecting the DNA molecule into the joint includes, but is not limited to, encapsulation of the DNA molecule into cationic liposomes or the direct injection of the DNA molecule itself into the joint. Expression of the heterologous gene of interest subsequent to in vivo transfection of the synovial tissue is ensured by inserting a promoter fragment active in eukaryotic cells directly upstream of the coding region of the heterologous gene. One of ordinary skill in the art may utilize known strategies and techniques of vector construction to ensure appropriate levels of expression subsequent to entry of the DNA molecule into the synovial tissue. As an example, and not a limitation, of the present invention, a DNA plasmid vector containing the interleukin-1 beta coding sequence ligated downstream of the CMV promoter was encapsulated within liposomes and injected into the knee joints of recipient rabbits. Interleukin-1 beta was expressed in synovial tissue, as significant amounts of

- 30 -

interleukin-1 beta was recovered from the synovial tissue within the region of intra-articular injection.

A further embodiment of this invention provides an additional method for introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for use in treating the mammalian host. This additional method includes employing the biologic means of utilizing a virus to deliver the DNA vector molecule to the target cell or tissue. Preferably, the virus is a psuedovirus, the genome having been altered such that the psuedovirus is capable only of delivery and stable maintenance within the target cell; but not retaining an ability to replicate within the target cell or tissue. The altered viral genome is further manipulated by recombinant DNA techniques such that the viral genome acts as a DNA vector molecule which contains the heterologous gene of interest to be expressed within the target cell or tissue. This method also includes employing as the gene a gene capable of encoding at least one of the materials selected from the group which includes (a) a human interleukin-1 receptor antagonist protein or biologically active derivative or fragment thereof, (b) a Lac Z marker gene capable of encoding a beta-galactosidase protein or biologically active derivative or fragment thereof, (c) a soluble interleukin-1 receptor protein or biologically active derivative or fragment thereof, (d) a proteinase inhibitor and (e) a soluble tumor necrosis factor receptor protein or a biologically active derivative or fragment thereof and (f) a cytokine.

The following examples are offered by way of illustration of the present invention, and not by way of limitation.

- 31 -

EXAMPLE IPackaging of AAV

5 The only cis-acting sequences required for
replication and packaging of recombinant adeno-associated
virus (AAV) vector are the AAV terminal repeats. Up to 4 kb
of DNA can be inserted between the terminal repeats without
effecting viral replication or packaging. The virus rep
proteins and viral capsid proteins are required in trans for
virus replication as is an adeno-associated virus helper. To
10 package a recombinant AAV vector, the plasmid containing the
terminal repeats and the therapeutic gene is co-transfected
into cells with a plasmid that expresses the rep and capsid
proteins. The transfected cells are then infected with
adeno-associated virus and virus isolated from the cells about
15 48-72 hours post-transfection. The supernatants are heated to
about 56° Centigrade to inactivate the adeno-associated virus,
leaving a pure virus stock of recombinant AAV.

EXAMPLE IIElectroporation

20 The connective tissue cells to be electroporated are
placed into HEPES buffer saline (HBS) at a concentration of
about 10^7 cells per ml. The DNA to be electroporated is added
at a concentration of about 5-20 ug/ml of HBS. The mixture is
placed into a cuvette and inserted into the cuvette holder
25 that accompanies the Bio-RAD electroporation device (1414
Harbour Way South, Richmond, CA 94804). A range between about
250 and 300 volts at a capacitance of about 960 ufarads is
required for introduction of DNA into most eukaryotic cell
types. Once the DNA and the cells are inserted into the
30 Bio-RAD holder, a button is pushed and the set voltage is
delivered to the cell-DNA solution. The cells are removed
from the cuvette and replated on plastic dishes.

- 32 -

EXAMPLE III

The cDNA encoding the human interleukin-1 receptor antagonist (IRAP) was inserted into the NcoI and BamHI cloning sites of the retroviral vector MFG as shown in Figure 1. Specifically, a PstI to BamHI fragment from the IRAP cDNA was linked to a synthetic oligonucleotide adapter from the NcoI site (representing the start site of translation for IRAP) to the PstI site (approximately 12 base pairs downstream from the NcoI site) to the MFG backbone digested at NcoI and BamHI in a three part ligation reaction. This three part ligation involving a synthetic oligo and two DNA fragments is well known by those skilled in the art of cloning. LTR means long terminal repeats, 5'SD means 5' splice donor, 3'SA means 3' splice acceptor. The straight arrow and the crooked arrow in Figure 1 represent unspliced and spliced messenger RNAs respectively. IRAP is encoded by the spliced message.

Figure 2 shows the cDNA encoding the human interleukin-1 receptor antagonist protein (IRAP) with a selectable neo gene marker. Figure 3 shows a low power micrograph of synovium recovered from the knee of a rabbit one month after intra-articular injection of Lac Z⁺, neo⁺ synoviocytes. Tissue was stained histochemically for the presence of beta-galactosidase. This micrograph counterstained with eosin revealed an area of intensely stained, transplanted cells demonstrating that these cells have colonized the synovial lining of the recipient joint.

EXAMPLE IVAnimal Models

The methods of this invention of transferring genes to the synovia of mammalian joints permit the production and analysis of joint pathologies that were not previously possible. This is because the only other way of delivering potentially arthrirogenic compounds to the joint is by intra-articular injection. Not only are such compounds

- 33 -

quickly cleared from joints, but the effects of bolus injections of these compounds do not accurately mimic physiological conditions where they are constantly produced over a long period of time. In contrast, the gene transfer technologies of this invention permit selected proteins of known or suspected involvement in the arthritic process to be expressed intra-articularly over an extended period of time, such as for example, at least a three month period. The animal models of this invention therefore permits the importance of each gene product to the arthritic process to be evaluated individually. Candidate genes include, but are not restricted to, those coding for cytokines such as interleukin-1 (IL-1) alpha, IL-1 beta, and TNF-alpha, and matrix metalloproteinases such as collagenases, gelatinases and stromelysins.

Additionally, the gene transfer techniques of this invention are suitable for use in the screening of potentially therapeutic proteins. In this use, the animal models of the invention are initiated in joints whose synovia express gene coding for potential anti-arthritic proteins. Candidate proteins include, but are not restricted to, inhibitors of proteinases such as, for example, the tissue inhibitor of metalloproteinases, and cytokines such as, for example, transforming growth factor-beta.

EXAMPLE V

Method For Using Synoviocytes As A Delivery System For Gene Therapy

Rabbits are killed by intravenous injection of 4 ml. nembutol, and their knees quickly shaved. Synovia are surgically removed from each knee under aseptic conditions, and the cells removed from their surrounding matrix by sequential digestion with trypsin and collagenase (0.2% w/v in Gey's Balanced Salt Solution) for about 30 minutes and about 2 hours, respectively. The cells recovered in this way are

- 34 -

seeded into 25 cm² culture flasks with about 4 ml of Ham's F₁₂ nutrient medium supplemented with 10% fetal bovine serum, about 100 U/ml penicillin and about 100) g/ml streptomycin, and incubated at about 37° in an atmosphere of 95% air, 5% CO₂.
5 Following about 3-4 days incubation, the cells attain confluence. At this stage, the culture medium is removed and the cell sheet washed twice with approximately 5 mls of Grey's Balanced Salt Solution to remove non-adherent cells such as lymphocytes. The adherent cells are then treated with trypsin
10 (0.25% w/v in balanced salt solution). This treatment detaches the fibroblastic, Type B synoviocytes, but leaves macrophages, polymorphonuclear leukocytes and the Type A synoviocytes attached to the culture vessel. The detached cells are recovered, re-seeded into 25 cm² culture vessels at
15 a 1:2 split ratio, medium is added and the culture returned to the incubator. At confluence this procedure is repeated.

After the third such passage, the cells are uniformly fibroblastic and comprise a homogeneous population of Type B synoviocytes. At this stage, cells are infected
20 with the retroviral vector.

Following infection, cells are transferred to fresh nutrient medium supplemented with about 1 mg/ml G418 (GIBCO/BRL, P.O. Box 68, Grand Island, NY 14072-0068) and returned to the incubator. Medium is changed every three
25 days as neo⁻ cells die and the neo⁺ cells proliferate and attain confluency. When confluent, the cells are trypsinized and subcultured as described above. One flask is set aside for staining with X-gal to confirm that the neo⁺ cells are also Lac Z⁺. When the subcultures are confluent, the medium
30 is recovered and tested for the presence of IRAP, soluble IL-1R or other appropriate gene products as hereinbefore described. Producing synoviocyte cultures are then ready for transplantation.

- 35 -

The day before transplantation, the cells are recovered by trypsinizing, as hereinbefore described. These cells are then suspended in nutrient medium, and incubated overnight in an untreated plastic centrifuge tube. Under these conditions, the cells do not adhere, but they regenerate their cell surface proteins that were removed by trypsinizing.

The following morning, the cells are recovered by centrifuging, washed several times by resuspension in Gey's Balanced Salt Solution and finally resuspended at a concentration of about 10^6 - 10^7 cells/ml in Grey's solution. Approximately 1 ml of this suspension is then introduced into the knee joint of a recipient rabbit by intra-articular injection. For this purpose a 1 ml syringe with a 25-gauge hypodermic needle is used. Injection is carried out through the patellar tendon. Experiments in which radioopaque dye was injected have confirmed that this method successfully introduces material into all parts of the joint.

EXAMPLE VI

The method of Example V for producing generally uniformly fibroblastic cells of a homogeneous population of Type B synoviocytes was followed to effect growing cultures of lapine synovial fibroblasts. These growing cultures of lapine synovial fibroblasts were subsequently infected with an amphotropic retroviral vector carrying marker genes coding for beta-galactosidase (Lac Z) and resistance to the neomycin analogue G418 (neo⁺). Following infection and growth in selective medium containing about 1 mg/ml G418, all cells stained positively in a histochemical stain for beta-galactosidase.

Neo selected cells carrying the Lac Z marker gene were transplanted back into the knees of recipient rabbits to examine the persistence and expression of these genes *in vivo*. Two weeks following transplantation, islands of Lac Z⁺ cells within the synovium of recipient knees were observed. This

- 36 -

confirmed the ability of the method of this invention to introduce marker genes into rabbit synovia and to express them in situ.

EXAMPLE VII

5 Neo-selected, Lac Z⁺ synoviocytes were recovered from cell culture, suspended in Gey's Balanced Salt Solution and injected intra-articularly into the knee joints of recipient rabbits (about 10⁵ - 10⁷ cells per knee). Contra-lateral control knees received only a carrier solution. At
10 intervals up to 3 months following transplant, the rabbits were killed and their synovia and surrounding capsule recovered. Each sample may be analyzed in three ways. A third of the synovium was stained histochemically en masse for the presence of beta-galactosidase. A second portion may be
15 used for immunocytochemistry using antibodies specific for bacterial beta-galactosidase. The final portion may be digested with trypsin and collagenase, and the cells thus recovered cultured in the presence of G418.

20 Staining of the bulk synovial tissue revealed extensive areas of Lac Z⁺ cells, visible to the naked eye. Control synovia remained colorless. Histochemical examination of synovia revealed the presence of islands of cells staining intensely positive for beta-galactosidase. These cells were present on the superficial layer of the synovial lining, and
25 were absent from control synovia. From such tissue it was possible to grow Lac Z⁺, neo⁺ cells. Cells recovered from control tissue were Lac Z⁻ and died when G418 was added to the culture. This indicates that the transplanted, transduced synovial fibroblasts have successfully recolonized the synovia
30 of recipient joints, and continue to express the two marker genes, Lac Z and neo. Maintaining intra-articular Lac Z and neo expression in transplanted synoviocytes has been effected for 3 months using primary cells and one month using the HIG-82 cell line.

- 37 -

EXAMPLE VIII

Based upon the methods of the hereinbefore presented examples, and employing standard recombinant techniques well known by those skilled in the art, the human IRAP gene was incorporated into an MFG vector as shown in Figure 1. Following the infection of synoviocyte cultures of rabbit origin with this viral vector, IRAP was secreted into the culture medium.

Western blotting, well known by those skilled in the art, was carried out using an IRAP-specific rabbit polyclonal antibody that does not recognize human or rabbit IL-1 alpha or IL-1 beta, or rabbit IRAP. Figure 4 shows a Western blot which sets forth the production of IRAP by four cultures of HIG-82 cells infected with MFG-IRAP. Three forms of the IRAP are present: a non-glycosylated form which runs with recombinant standards, and two larger glycosylated forms. The results of the Western blotting shown in Figure 4 demonstrated that IRAP was produced by HIG-82 synoviocyte cell line (Georgescu, 1988) following infection with the MFG-IRAP vector of this invention. The Western blotting of Figure 4 shows the IRAP concentration of the conditioned medium is as high as 50 ng/ml. This is approximately equal to 500 ng IRAP/10⁶ cells/day. Lane 1 and Lane 2 of Figure 4 show that the recipient synovia tissue secrete substantial amounts of HIG-IRAP at 3 days (Lane 2) and 6 days (Lane 1). Lane 3 shows human recombinant IRAP. Lane 6 indicates that rabbit synovial cells produce a larger glycosylated version of this molecule after infection with MFG-IRAP. Lane 7 indicates that native rabbit synovial cells do not produce this glycosylated form.

Figure 5 shows that medium conditioned by IRAP⁺ synoviocytes blocks the induction of neutral metalloproteinases in articular chondrocytes exposed to recombinant human IL-1 beta. Chondrocytes normally secrete 1 U/10⁶ cells, or less, gelatinase into their culture media. Figure 5 shows

- 38 -

that when to about 5 U/ml or 10 U/ml IL-1 are added, gelatinase production increases to over 4 U and 6U/10⁸ cells, respectively. Addition of medium conditioned by MFG-IRAP-infected HIG-82 cells employed by the method of this invention suppressed gelatinase production by IL-1 treated chondrocytes. With 5 U/ml IL-1 (Figure 5, right panel) inhibition was 100% for one culture and 41% for the other. With 10 U/ml IL-1, inhibition was reduced to 38% and 18% (Figure 5, left panel) as is expected of a competitive inhibitor. These data demonstrate that the IRAP produced by HIG-82 cells infected with MFG-IRAP is biologically active.

EXAMPLE IX

This example demonstrates the uptake and expression of Lac Z gene by synoviocytes using infection by a liposome (lipofection). A six well plate containing synoviocyte cultures were transduced with the Lac Z gene by lipofection. The content of each well is as follows:

Well 1	Control cells, treated with liposomes alone
Well 2	Control cells, treated with DNA alone
Well 3	DNA + 150 nmole liposomes
Well 4	DNA + 240 nmole liposomes
Well 5	DNA + 300 nmole liposomes
Well 6	DNA + 600 nmole liposomes

Wells 3-6 containing sub-confluent cultures of synovial fibroblasts were infected with 6 ug of DNA complexed with 150-600 nmoles/well of "DC-chol" liposome or in the alternative, with "SF-chol". Three days later, cells were stained histochemically for expression of beta-galactosidase (Figure 6).

Table 1 shows the results of using the liposomes "DC-chol" and "SF-chol" in converting synoviocyte cultures to the Lac Z⁺ phenotype without selection. Table 1 sets forth that the "DC-chol" liposome in a concentration of about 300 nmole/well converted generally 30% of the synovial cells in

- 39 -

synoviocyte cultures to the Lac Z⁺ phenotype without selection. Reduced expression was shown in Well 6 for "DC-chol" due to the toxic effect of the high liposome concentration.

In another embodiment of this invention, a gene and method of using this gene provides for the neutralization of interleukin-1. Interleukin-1 is a key mediator of cartilage destruction in arthritis. Interleukin-1 also causes inflammation and is a very powerful inducer of bone resorption. Many of these effects result from the ability of interleukin-1 to increase enormously the cellular synthesis of prostaglandin E₂, the neutral proteinases -- collagenase, gelatinase, and stromelysin, and plasminogen activator. The catabolic effects of interleukin-1 upon cartilage are exacerbated by its ability to suppress the synthesis of the cartilaginous matrix by chondrocytes. Interleukin-1 is present at high concentrations in synovial fluids aspirated from arthritic joints and it has been demonstrated that intra-articular injection of recombinant interleukin-1 in animals causes cartilage breakdown and inflammation.

Interleukin-1 exists as several species, such as unglycosylated polypeptide of 17,000 Daltons. Two species have previously been cloned, interleukin-1 alpha and

- 40 -

interleukin-1 beta. The alpha form has a pI of approximately 5, and the beta form has a pI around 7. Despite the existence of these isoforms, interleukin-1 alpha and interleukin-1 beta have substantially identical biological properties and share common cell surface receptors. The type I interleukin-1 receptor is a 80kDa (kilodalton) glycoprotein and contains an extracellular, interleukin-1 binding portion of 319 amino acids which are arranged in three immunoglobulin-like domains held together by disulfide bridges as shown in Figure 7. A 21 amino acid trans-membrane domain joins the extracellular portion to the 217 amino acid cytoplasmic domain. Figures 8A-8C show the amino acid and nucleotide sequence of the human and mouse interleukin-1 receptors. In Figure 8B, the 21 amino acid trans-membrane region of the interleukin-1 receptor is marked by the thicker solid line. In Figures 8A and 8B, the position of the 5' and 3' oligonucleotides for PCR are marked by thinner short lines, respectively. The lysine amino acid just 5' to the trans-membrane domain to be mutated to a stop codon is marked by a solid circle in Figure 8B.

Synovium is by far the major, and perhaps the only, intra-articular source of interleukin-1 in the arthritic joint. Synovia recovered from arthritic joints secrete high levels of interleukin-1. Both the resident synoviocytes and infiltrating blood mononuclear cells within the synovial lining produce interleukin-1.

The present invention provides a method of using in vivo a gene coding for a truncated form of the interleukin-1 receptor which retains its ability to bind interleukin-1 with high affinity but which is released extracellularly and therefore inactive in signal transduction. The binding of this truncated and modified receptor to interleukin-1 inhibits the intra-articular activity of interleukin-1.

This method of using a gene encoding the extracellular interleukin-1 binding domain of an interleukin-1

- 41 -

receptor that is capable of binding to and neutralizing interleukin-1 includes employing a retroviral vector carrying a truncated interleukin-1 receptor gene which encodes a truncated and soluble active form of the receptor. The expression of the novel interleukin-1 receptor gene is controlled by regulatory sequences contained within the vector that are active in eukaryotic cells. This recombinant viral vector is transfected into cell lines stably expressing the viral proteins in trans required for production of infectious virus particles carrying the recombinant vector. These viral particles are used to deliver the recombinant interleukin-1 receptor to the recipient synovial cells by direct virus infection in vivo.

The soluble human interleukin-1 receptor to be inserted into the retroviral vector may be generated by a polymerase chain reaction (PCR). An oligonucleotide complementary to the 5' leader sequence of the human interleukin-1 receptor (GCGGATCCCCTCCTAGAAGCT) and an oligonucleotide complementary to a region just upstream from the transmembrane domain of the interleukin-1 receptor (GCGGATCCCATGTGCTACTGG) are used as primers for PCR. The primer for the region of the interleukin-1 receptor adjacent to the trans-membrane domain contains a single base change so that the lys codon at amino acid 319 (AAG) is changed to a stop codon (TAG). By inserting a translation stop codon just upstream from the transmembrane domain, a truncated form of interleukin-1 receptor that is secreted by the cell is generated. A BamHI recognition sequence (GGATCC) is added to the 5' end of the PCR primers, and following amplification, the resulting interleukin-1 receptor fragment is cloned into a BamHI site. A cDNA library from human T-cells is used as a source for the interleukin-1 receptor cDNA. To amplify the appropriate region of the interleukin-1 receptor from the cDNA library, the complementary primers are added to the DNA and 50

- 42 -

cycles of annealing, primer extension and denaturation are performed using a thermocycler and standard PCR reaction conditions well known by those persons skilled in the art. Following amplification of the interleukin-1 soluble receptor using the PCR process, the resulting fragment is digested with BamHI and inserted into the pLJ retroviral vector. The pLJ retroviral vector is available from A. J. Korman and R. C. Mulligan. See also Proc. Natl. Acad. Sci., Vol. 84, pp. 2150-2154 (April 1987) co-authored by Alan J. Korman, J. Daniel Frantz, Jack L. Strominger and Richard C. Mulligan. Restriction analysis was performed to determine the correct orientation of the insert.

The retrovirus vector carrying the truncated interleukin-1 receptor is transferred into the CRIP (Proc. Natl. Acad. Sci., Vol. 85, pp. 6460-6464 (1988), O. Danos and R. C. Mulligan) packaging cell line using a standard CaPO₄ transfection procedure and cells wherein the viral vector is stably integrated and is selected on the basis of resistance to the antibiotic G418. The viral vector containing the neomycin resistant (neo-r) gene is capable of imparting resistance of the cell line to G418. The CRIP cell line expresses the three viral proteins required for packaging the vector viral RNAs into infectious particles. Moreover, the viral particles produced by the CRIP cell line are able to efficiently infect a wide variety of mammalian cell types including human cells. All retroviral particles produced by this cell line are defective for replication but retain the ability to stably integrate into synovial cells thereby becoming an heritable trait of these cells. Virus stocks produced by this method are substantially free of contaminating helper-virus particles and are also non-pathogenic.

More specifically, the truncated interleukin-1 gene can be inserted into a retroviral vector under the regulation

- 43 -

of a suitable eukaryotic promoter such as the retroviral promoter already contained within the gene transfer vector, such as for example, the pLJ vector shown in Figure 9. Figure 9 shows the structure of the pLJ interleukin receptor retroviral vector and partial restriction endonuclease map. Reference numeral 10 shows the interleukin-1 receptor inserted into a retroviral vector. Reference numeral 12 indicates long terminal repeats (LTR's) at each end of the structure of the pLJ interleukin receptor retroviral vector shown in Figure 8. These LTR's regulate the viral transcription and expression of the interleukin-1 receptor. Bacterial gene encoding resistance to the antibiotic neomycin (neo-r) is shown at reference numeral 16. The Simian Virus 40 enhancer promoter (SV 40) is indicated at reference numeral 18, and regulates the expression of the neo-r gene. Reference numbers 20 and 22, respectively, show the sites wherein the resulting interleukin receptor fragment is cloned. It will be understood by those persons skilled in the art that other vectors containing different eukaryotic promoters may also be utilized to obtain a generally maximal level of interleukin-1 receptor expression. The vectors containing the truncated, and modified interleukin-1 receptor will be introduced into a retroviral packaging cell line (CRIP) by transfection and stable transformants isolated by selection for the expression of the neomycin resistance gene also carried by the pLJ vector. The CRIP cell line expresses all the proteins required for packaging of the exogenous retroviral RNA. Viral particles produced by the G418-selected CRIP cell lines will carry a recombinant retrovirus able to infect mammalian cells and stably express the interleukin-1 truncated receptor. The viral particles are used to infect synovial cells directly in vivo by injecting the virus into the joint space.

Another embodiment of this invention provides a method for using the hereinbefore described viral particles to

- 44 -

infect in culture synovial cells obtained from the lining of the joint of a mammalian host. The advantage of the infection of synovial cells in culture is that infected cells harboring the interleukin-1 receptor retroviral construct can be selected using G418 for expression of the neomycin resistance gene. The infected synovial cells expressing the interleukin-1 receptor can then be transplanted back into the joint by intra-articular injection. The transplanted cells will express high levels of soluble interleukin-1 receptor in the joint space thereby binding to and neutralizing substantially all isoforms of interleukin-1, including interleukin-1 alpha and interleukin-1 beta.

The method used for transplantation of the synovial cells within the joint is a routine and relatively minor procedure used in the treatment of chronic inflammatory joint disease. Although synovium can be recovered from the joint during open surgery, it is now common to perform synovectomies, especially of the knee, through the arthroscope. The arthroscope is a small, hollow rod inserted into the knee via a small puncture wound. In addition to permitting the intra-articular insertion of a fibre-optic system, the arthroscope allows access to surgical instruments, such that synovial tissue can be removed arthroscopically. Such procedures can be carried out under "spinal" anesthetic and the patient allowed home the same day. In this manner sufficient synovium can be obtained from patients who will receive this gene therapy.

The synovial cells (synoviocytes) contained within the excised tissue may be aseptically recovered by enzymic digestion of the connective tissue matrix. Generally, the synovium is cut into pieces of approximately 1 millimeter diameter and digested sequentially with trypsin (0.2% w/v in Grey's Balanced Salt Solution) for 30 minutes at 37° Centigrade, and collagenase (0.2% w/v in Grey's Balanced Salt

- 45 -

Solution) for 2 hours at 37° Centigrade. Cells recovered from this digestion are seeded into plastic culture dishes at a concentration of 10^4 - 10^5 cells per square centimeter with Hank's F₁₂ medium supplemented with 10% fetal bovine serum and antibiotics. After 3-7 days, the culture medium is withdrawn. Non-adherent cells such as lymphocytes are removed by washing with Gey's Balanced Salt Solution and fresh medium added. The adherent cells can now be used as they are, allowed to grow to confluency or taken through one or more subcultures. Subcultivating expands the cell number and removes non-dividing cells such as macrophages.

Following genetic manipulation of the cells thus recovered, they can be removed from the culture dish by trypsinizing, scraping or other means, and made into a standard suspension. Gey's Balanced Salt Solution or other isotonic salt solutions of suitable composition, or saline solution are suitable carriers. A suspension of cells can then be injected into the recipient mammalian joint. Intra-articular injections of this type are routine and easily carried out in the doctor's office. No surgery is necessary. Very large numbers of cells can be introduced in this way and repeat injections carried out as needed.

Another embodiment of this invention is the gene produced by the hereinbefore described method of preparation. This gene carried by the retrovirus may be incorporated in a suitable pharmaceutical carrier, such as for example, buffered physiologic saline, for parenteral administration. This gene may be administered to a patient in a therapeutically effective dose. More specifically, this gene may be incorporated in a suitable pharmaceutical carrier at a therapeutically effective dose and administered by intra-articular injection.

In another embodiment of this invention, this gene may be administered to patients as a prophylactic measure to

- 46 -

prevent the development of arthritis in those patients determined to be highly susceptible of developing this disease. More specifically, this gene carried by the retrovirus may be incorporated in a suitable pharmaceutical carrier at a prophylactically effective dose and administered by parenteral injection, including intra-articular injection.

EXAMPLE X

Fifty micrograms of a DNA plasmid vector molecule containing the interleukin-1 beta coding sequence ligated downstream of the CMV promoter was encapsulated within cationic liposomes, mixed with Geys biological buffer and injected intra-articularly into the knee joints of a rabbit. Forty eight hours subsequent to injection one nanogram of interleukin-1 beta was recovered from the knee joint area. Therefore, injection of the DNA containing liposome solution within the region of the synovial tissue prompted fusion of the liposomes to the synovial cells, transfer of the DNA plasmid vector into synovial cells and subsequent expression of the IL-1 beta gene. Additionally, it is possible to inject non-encapsulated (i.e., naked) DNA into the joint area and monitor transfection of the DNA vector into the synovial cells as determined by subsequent expression of the IL-1 beta gene in synovial cells. Therefore, either method may be utilized as a plausible alternative to the in vitro manipulation of synovia also exemplified in the present invention.

It will be appreciated by those skilled in the art that this invention provides a method of introducing into a connective tissue cell of a mammalian host in vitro, or in the alternative in vivo, at least one gene which codes for proteins with therapeutic properties. This method includes employing genes having DNA that is capable of maintenance and expression.

It will be appreciated by those skilled in the art that this invention provides a method of introducing at least

- 47 -

one gene encoding a product into at least one cell of the connective tissue of a mammalian host for treating an arthritic condition of the mammalian host.

5 It will be understood by those skilled in the art that this invention provides a method to repair and regenerate the connective tissue of a mammalian host.

It will be further understood that this invention provides a method to produce an animal model for the study of connective tissue pathology.

10 It will be appreciated by those persons skilled in the art that this invention provides a method of using and a method of preparing a gene encoding an extra cellular interleukin-1 binding domain of an interleukin-1 receptor that is capable of binding to and neutralizing substantially all
15 isoforms of interleukin-1, and thus substantially protect cartilage of a mammalian host from pathological degradation. In addition, it will be understood by those persons skilled in the art that the method of using the gene of this invention will reduce inflammation, protect soft tissues of the joint
20 and suppress the loss of bone that occurs in patients suffering with arthritis.

It will be appreciated by those persons skilled in the art that the viral vectors employed in the hereinbefore described invention may be employed to transfect synovial
25 cells in vivo or in culture, such as by direct intra-articular injection or transplantation of autologous synovial cells from the patient transduced with the retroviral vector carrying the truncated interleukin-1 receptor gene.

Whereas particular embodiments of this invention
30 have been described above for purposes of illustration, it will be evident to those persons skilled in the art that numerous variations of the details of the present invention may be made without departing from the invention as defined in the appended claims.

WE CLAIM:

1. A method of introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for use in treating said mammalian host which comprises:
 - 5 employing recombinant techniques to produce a viral vector which contains said gene encoding for said product; and
 - 10 infecting said connective tissue cell of said mammalian host using said viral vector containing said gene coding for said product.
2. The method of Claim 1, including introducing said gene encoding said product into at least one cell of said connective tissue of said mammalian host for a therapeutic use.
3. The method of Claim 1, including employing as said
15 gene a gene capable of encoding a human interleukin-1 receptor antagonist protein.
4. The method of Claim 1, including employing as said gene a Lac Z marker gene capable of encoding a beta-galactosidase.
5. The method of Claim 1, including employing as said
20 gene a gene capable of encoding a soluble interleukin-1 receptor.
6. The method of Claim 1, including employing as said gene a gene capable of encoding at least one proteinase inhibitor.
7. The method of Claim 5, including employing a tissue inhibitor of metalloproteinases as said proteinase inhibitor.
8. The method of Claim 1, including employing as said
25 gene a gene capable of encoding at least one cytokine.
9. The method of Claim 8, including employing as said cytokine at least one material selected from the group consisting of interleukin-1 alpha, interleukin-1 beta, interleukin-2,
30 interleukin-3, interleukin-4, interleukin-5, interleukin-6, interleukin-7, interleukin-8, interleukin-9, interleukin-10, interleukin-11, interleukin-12, tumor necrosis factor α , and tumor necrosis factor β .
10. The method of Claim 8, including employing as said
35 cytokine at least one transforming growth factor.

- 61 -

11. The method of Claim 10, including employing as said transforming growth factor a growth factor selected from the group consisting of TGF-beta₁, TGF-beta₂, TGF-beta₃, and TGF-alpha.

12. The method of Claim 8, including employing as said
5 cytokine at least one fibroblast growth factor.

13. The method of Claim 1, including employing as said viral vector a retroviral vector.

14. The method of Claim 13, including employing as said retroviral vector at least one material selected from the group
10 consisting of MFG and BAG.

15. The method of Claim 14 including employing as said gene a gene capable of encoding a human interleukin-1 receptor antagonist protein and employing MFG as said retroviral vector.

16. The method of Claim 14, including employing a Lac Z
15 marker gene as said gene capable of encoding a beta-galactosidase and employing MFG as said retroviral vector.

17. The method of Claim 14, including employing a Lac Z neo marker gene as said gene capable of encoding a beta-galactosidase and employing BAG as said retroviral vector.

18. The method of Claim 14, including employing as said
20 gene a gene capable of encoding a soluble interleukin-1 receptor.

19. The method of Claim 14, including employing as said gene a gene capable of encoding at least one proteinase inhibitor.

20. The method of Claim 19, including employing a tissue
25 inhibitor of metalloproteinases as said proteinase inhibitor.

21. The method of Claim 14, including employing as said gene a gene capable of encoding at least one cytokine.

22. The method of Claim 21, including employing as said cytokine at least one material selected from the group consisting
30 of interleukin-1 alpha, interleukin-1 beta, interleukin-2, interleukin-3, interleukin-4, interleukin-5, interleukin-6, interleukin-7, interleukin-8, interleukin-9, interleukin-10, interleukin-11, interleukin-12, tumor necrosis factor α , and tumor necrosis factor β .

23. The method of Claim 21, including employing as said
35 cytokine at least one transforming growth factor.

- 62 -

24. The method of Claim 23, including employing as said transforming growth factor a growth factor selected from the group consisting of TGF-beta₁, TGF-beta₂, TGF-beta₃, and TGF-alpha.

5 25. The method of Claim 21, including employing as said cytokine at least one fibroblast growth factor.

26. The method of Claim 1, including employing as said viral vector at least one vector from the group consisting of an adeno-associated virus, adenovirus and a herpes virus.

10 27. The method of Claim 26, including employing as said gene a gene capable of encoding a human interleukin-1 receptor antagonist protein.

28. The method of Claim 26, including employing as said gene a gene capable of encoding a soluble interleukin-1 receptor.

15 29. The method of Claim 26, including employing as said gene a Lac Z marker gene capable of encoding a beta-galactosidase.

30. The method of Claim 26, including employing as said gene a gene capable of encoding at least one proteinase inhibitor.

31. The method of Claim 30, including employing a tissue inhibitor of metalloproteinases as said proteinase inhibitor.

20 32. The method of Claim 26, including employing as said gene a gene capable of encoding at least one cytokine.

33. The method of Claim 32, including employing as said cytokine at least one material selected from the group consisting of interleukin-1 alpha, interleukin-1 beta, interleukin-2, 25 interleukin-3, interleukin-4, interleukin-5, interleukin-6, interleukin-7, interleukin-8, interleukin-9, interleukin-10, interleukin-11, and interleukin-12, tumor necrosis factor α , and tumor necrosis factor β .

30 34. The method of Claim 32, including employing as said cytokine at least one transforming growth factor.

35. The method of Claim 34, including employing as said transforming growth factor a growth factor selected from the group consisting of TGF-beta₁, TGF-beta₂, TGF-beta₃, and TGF-alpha.

36. The method of Claim 33, including employing as said 35 cytokine at least one fibroblast growth factor.

- 63 -

37. The method of Claim 1, including introducing said gene into said connective tissue which tissue is selected from the group consisting of a ligament, a cartilage, a tendon, and a synovium.

5 38. The method of Claim 37, including employing a cruciate ligament as said ligament.

39. The method of Claim 38, including employing as said cruciate ligament a ligament selected from the group consisting of an anterior cruciate ligament and a posterior cruciate ligament.

10 40. The method of Claim 1, including employing as said gene a gene having DNA that is capable of maintenance and expression.

41. The method of Claim 1, including introducing said gene into said cell in vitro.

15 42. The method of Claim 41, including subsequently transplanting said infected cell into said mammalian host.

43. The method of Claim 41, including after said infecting of said connective tissue cell and before said transplanting of said infected cell into said mammalian host, storing said infected connective tissue cell.

20 44. The method of Claim 43, including storing said infected connective tissue cell in 10% DMSO under liquid nitrogen.

45. The method of Claim 42, including employing said method to substantially prevent the development of arthritis in a mammalian host having a high susceptibility of developing arthritis.

46. The method of Claim 42, including employing said method on an arthritic mammalian host for a therapeutic use.

30 47. The method of Claim 42, including employing said method to repair and regenerate said connective tissue which tissue is selected from the group consisting of a ligament, a cartilage, a tendon, and a synovium.

48. The method of Claim 47, including employing said method on a mammalian host that is a human being.

35 49. The method of Claim 1 including effecting in vivo said infection of said cell by introducing said viral vector

- 64 -

containing said gene coding for said product directly into said mammalian host.

50. The method of Claim 49, including effecting said direct introduction into said mammalian host by intra-articular injection.

51. The method of Claim 49, including employing said method to substantially prevent the development of arthritis in a mammalian host having a high susceptibility of developing arthritis.

52. The method of Claim 49, including employing said method on an arthritic mammalian host for a therapeutic use.

53. The method of Claim 49, including employing said method to repair and regenerate said connective tissue which tissue is selected from the group consisting of a ligament, a cartilage, a tendon, and a synovium.

54. The method of Claim 49, including employing said method on a mammalian host that is a human being.

55. A method of introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for use in treating said mammalian host which comprises:

employing non-viral means for introducing said gene encoding for said product into said connective tissue cell, said non-viral means being selected from the group consisting of at least one liposome, $\text{Ca}_3(\text{PO}_4)_2$, electroporation, and DEAE-dextran.

56. The method of Claim 55, including employing as said liposome a material selected from the group consisting of DC-cholesterol and SF-cholesterol.

57. The method of Claim 55, including employing as said gene a gene capable of encoding a human interleukin-1 receptor antagonist protein.

58. The method of Claim 55, including employing a Lac Z marker gene as said gene capable of encoding a beta-galactosidase.

59. The method of Claim 55, including employing as said gene a gene capable of encoding an interleukin-1 soluble receptor.

- 65 -

60. The method of Claim 55, including employing as said gene a gene capable of encoding at least one proteinase inhibitor.

61. The method of Claim 60, including employing a tissue inhibitor of metalloproteinases as said proteinase inhibitor.

5 62. The method of Claim 55, including employing as said gene a gene capable of encoding at least one cytokine.

63. The method of Claim 62, including employing as said cytokine at least one material selected from the group consisting of interleukin-1 alpha, interleukin-1 beta, interleukin-2,
10 interleukin-3, interleukin-4, interleukin-5, interleukin-6, interleukin-7, interleukin-8, interleukin-9, interleukin-10, interleukin-11, and interleukin-12, tumor necrosis factor α , and tumor necrosis factor β .

64. The method of Claim 62, including employing as said
15 cytokine at least one transforming growth factor.

65. The method of Claim 64, including employing as said transforming growth factor a growth factor selected from the group consisting of TGF-beta₁, TGF-beta₂, TGF-beta₃, and TGF-alpha.

66. The method of Claim 62, including employing as said
20 cytokine at least one fibroblast growth factor.

67. The method of Claim 55, including introducing said gene into connective tissue which tissue is selected from the group consisting of a ligament, a cartilage, a tendon, and a synovium.

68. The method of Claim 67, including employing a
25 cruciate ligament as said ligament.

69. The method of Claim 68, including employing as said cruciate ligament a ligament selected from the group consisting of an anterior cruciate ligament and a posterior cruciate ligament.

70. The method of Claim 55, including employing as said
30 gene a gene having DNA that is capable of maintenance and expression.

71. The method of Claim 55, including introducing said gene into said cell in vitro.

72. The method of Claim 71, including subsequently
35 transplanting said cell having said gene into said mammalian host.

73. The method of Claim 72, including

- 66 -

after said introducing of said gene encoding for said product into said connective tissue cell and before said transplanting of said connective tissue cell having said gene into said mammalian host, storing said connective tissue cell having said gene.

5 74. The method of Claim 73, including storing said connective tissue cell having said gene in 10% DMSO under liquid nitrogen.

10 75. The method of Claim 72, including employing said method to substantially prevent the development of arthritis in a mammalian host having a high susceptibility of developing arthritis.

76. The method of Claim 72, including employing said method on an arthritic mammalian host for a therapeutic use.

15 77. The method of Claim 72, including employing said method to repair and regenerate said connective tissue which tissue is selected from the group consisting of a ligament, a cartilage, a tendon, and a synovium.

20 78. A method of introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for use in treating said mammalian host which comprises:

25 employing non-viral means in vivo for directly introducing said gene encoding for said product into said connective tissue cell of said mammalian host, said non-viral means selected from the group consisting of at least one liposome, $\text{Ca}_3(\text{PO}_4)_2$, and DEAE-dextran.

79. The method of Claim 78, including effecting said in vivo introduction into said mammalian host by intra-articular injection.

30 80. The method of Claim 78, including employing said method to substantially prevent the development of arthritis in a mammalian host having a high susceptibility of developing arthritis.

35 81. The method of Claim 78, including employing said method on an arthritic mammalian host for a therapeutic use.

- 67 -

82. The method of Claim 78, including employing said method to repair and regenerate said connective tissue which tissue is selected from the group consisting of a ligament, a cartilage, a tendon, and a synovium.

5 83. A method to produce an animal model for the study of connective tissue pathology which comprises:

introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host comprising (a) employing recombinant techniques to produce a viral vector which contains said gene encoding for said product and (b) infecting said connective tissue cell of said mammalian host using said viral vector containing said gene coding for said product for effecting said animal model.

10 84. The method of Claim 83, including employing as said gene a material selected from the group consisting of a cytokine and a proteinase.

85. The method of Claim 84, including employing as said cytokine a material selected from the group consisting of interleukin-1 alpha, interleukin-1 beta, and TNF-alpha.

20 86. The method of Claim 84, including employing as said proteinase a matrix metalloproteinase.

87. The method of Claim 83, including employing as said matrix metalloproteinase an enzyme selected from the group consisting of a collagenase, a gelatinase, and a stromelysin.

25 88. A method to produce an animal model for the study of connective tissue pathology which comprises:

employing non-viral means for introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for effecting said animal model, said non-viral means being selected from the group consisting of at least one liposome, $\text{Ca}_3(\text{PO}_4)_2$, electroporation, and DEAE-dextran.

30 89. The method of Claim 88, including employing as said gene a material selected from the group consisting of a cytokine and a proteinase.

- 68 -

90. The method of Claim 89, including employing as said cytokine a material selected from the group consisting of interleukin-1 alpha, interleukin-1 beta, and TNF-alpha.

5 91. The method of Claim 89, including employing as said proteinase a matrix metalloproteinase.

92. The method of Claim 91, including employing as said matrix metalloproteinase an enzyme selected from the group consisting of a collagenase, a gelatinase, and a stromelysin.

10 93. A method of using a gene coding for a truncated interleukin-1 receptor to resist deleterious pathological changes associated with arthritis which comprises:

employing recombinant techniques to produce a retroviral packaging cell line which contain said gene coding for said truncated interleukin-1 receptor;

15 inserting said gene coding for said truncated interleukin-1 receptor into a retroviral vector wherein said retroviral vector is under the regulation of a suitable eukaryotic promoter;

transfecting said retroviral vector containing said gene coding for said truncated interleukin-1 receptor into said retroviral packaging cell line for the production of a viral particle that is capable of expressing said gene coding for said truncated interleukin-1 receptor; and

infecting synovial cells of a mammalian host using said viral particle obtained from said retroviral packaging cell line.

25 94. The method of Claim 93, employing said gene having DNA that is capable of replication and expression in said synovial cells lining a joint space of said mammalian host.

95. The method of Claim 93, including employing said method to substantially prevent the development of arthritis in a patient having a high susceptibility of developing arthritis.

30 96. The method of Claim 93, including employing said method to treat an arthritic patient.

97. The method of Claim 93, including effecting the infection of said synovial cells of a mammalian host by introducing said viral particle directly into said synovial cells lining a joint space of said mammalian host.

35

- 69 -

98. The method of Claim 97, including effecting said introduction of said viral particle by parenteral injection.

99. The method of Claim 97, including effecting said introduction of said viral particle by intra-articular injection.

5 100. The method of Claim 93, including effecting said infection of said synovial cells of a mammalian host by introducing said viral particles directly into synovial cells in culture to form transduced synovial cells which may be subsequently transplanted into a patient's joint.

10 101. The method of Claim 100, including effecting said transplantation of said transduced synovial cells into a patient's joint by employing intra-articular injection.

15 102. The method of Claim 93, including effecting said infection of said synovial cells of a mammalian host by introducing said viral particles into other synovial cells.

20 103. A method of using a gene coding for a extracellular interleukin-1 binding domain of an interleukin-1 receptor that is capable of binding to and neutralizing interleukin-1 which comprises:

25 employing recombinant techniques to produce a retrovirus vector carrying two genes wherein a first gene encodes said extracellular interleukin-1 binding domain of said interleukin-1 receptor and a second gene encodes for selectable antibiotic resistance; and

30 transfecting said retrovirus vector into a retrovirus packaging cell line to obtain a cell line producing nonpathogenic, replication deficient but integration competent, amphotrophic infectious retroviral particles carrying said gene.

35 104. The method of Claim 103, including initiating introduction of said gene by infection with said retroviral particles from said cell line directly into synovial cells lining a joint space of a mammalian host.

105. The method of Claim 103, including initiating introduction of said gene by transduction of autologous synovial cells in culture, selecting a synoviocyte cell line by treatment

- 70 -

of cultures with antibiotic, and transplanting said selected synoviocyte cells into an affected mammalian joint.

106. The method of Claim 103, wherein effecting said introduction of said viral particles is by parenteral injection.

5 107. The method of Claim 103, wherein effecting said introduction of said viral particles is by intra-articular injection.

108. A method for preparing a gene encoding an extracellular interleukin-1 binding domain of an interleukin-1 receptor that is capable of binding to and neutralizing interleukin-1 which comprises:

synthesizing said gene by a polymerase chain reaction of said extracellular interleukin-1 binding domain including a signal sequence for secretion of a protein;

15 introducing amplified interleukin-1 receptor coding sequence into a retroviral vector;

transfecting said retroviral vector into a amphitrophic retrovirus packaging cell line; and

20 collecting viral particles obtained from said retrovirus packaging cell line, wherein said viral particles contain said gene.

109. The gene prepared by the process of Claim 108.

110. A compound for parenteral administration to a patient in a therapeutically effective amount which comprises a gene encoding an extracellular interleukin-1 binding domain of an interleukin-1 receptor and a suitable pharmaceutical carrier.

111. A compound for parenteral administration to a patient in a prophylactically effective amount which comprises a gene encoding an extracellular interleukin-1 binding domain of an interleukin-1 receptor and a suitable pharmaceutical carrier.

112. A method of introducing at least one gene encoding a product into at least one cell of a synovial tissue of a mammalian host for use in treating said mammalian host which comprises:

35 employing recombinant DNA techniques to produce a DNA vector molecule which contains said gene encoding said product; and

- 71 -

injecting said DNA vector molecule into a joint of said mammalian host, said DNA vector molecule subsequently contacting said synovial cell.

5 113. The method of claim 112 wherein said DNA vector molecule is introduced prophylactically.

114. The method of claim 112 wherein the DNA vector molecule is encapsulated within liposomes prior to said injection into said joint.

10 115. The method of claim 113 wherein the DNA vector molecule is encapsulated within liposomes prior to said injection into said joint.

116. The method of claim 114, wherein the DNA vector molecule is a plasmid.

15 117. The method of claim 115, wherein the DNA vector molecule is a plasmid.

118. The method of Claim 112, including employing as said gene a gene capable of encoding a human interleukin-1 receptor antagonist protein.

20 119. The method of Claim 112, including employing as said gene a gene capable of encoding a soluble interleukin-1 receptor.

120. The method of Claim 112, including employing as said gene a Lac Z marker gene capable of encoding a beta-galactosidase.

121. The method of Claim 112, including employing as said gene a gene capable of encoding at least one proteinase inhibitor.

25 122. The method of Claim 121, including employing a tissue inhibitor of metalloproteinases as said proteinase inhibitor.

123. The method of Claim 112, including employing as said gene a gene capable of encoding at least one cytokine.

30 124. The method of Claim 123, including employing as said cytokine at least one material selected from the group consisting of interleukin-1 alpha, interleukin-1 beta, interleukin-2, interleukin-3, interleukin-4, interleukin-5, interleukin-6, interleukin-7, interleukin-8, interleukin-9, interleukin-10, interleukin-11, and interleukin-12, tumor necrosis factor α , and
35 tumor necrosis factor β .

- 72 -

125. The method of Claim 124, including employing as said cytokine at least one transforming growth factor.

126. The method of Claim 125, including employing as said transforming growth factor a growth factor selected from the group consisting of TGF-beta₁, TGF-beta₂, TGF-beta₃, and TGF-alpha.

127. The method of claim 112, including employing as said gene a gene capable of encoding a soluble tumor necrosis factor receptor.

128. The method of claim 124 wherein said gene encoding interleukin-1 beta is located proximally downstream from a CMV promoter fragment.

129. A method of introducing at least one gene encoding a product into at least one cell of a connective tissue of a mammalian host for use in treating said mammalian host which comprises:

employing recombinant techniques to produce a DNA vector molecule which contains said gene encoding for said product; and infecting said connective tissue cell of said mammalian host using a pseudovirus containing said DNA vector molecule.

130. The method of Claim 129 wherein the DNA vector is an altered viral genomic molecule, such that said DNA vector contains the heterologous gene of interest to be expressed in at least one cell of said connective tissue of said mammalian host.

131. The method of claim 26 wherein said herpes simplex virus vector is selected from the group consisting of herpes simplex type 1 and herpes simplex type 2.

132. The method of claim 100 wherein the synovial cells are synoviocytes removed from the joint.

133. The method of claim 132 wherein the synoviocytes are removed from the knee joint.

134. The method of claim 100 wherein the synovial cells are skin cells.

135. The method of claim 1, including employing as said gene a gene capable of encoding a soluble tumor necrosis factor receptor.

- 73 -

136. The method of claim 14, including employing as said gene a gene capable of encoding a soluble tumor necrosis factor receptor.

5 137. The method of claim 26, including employing as said gene a gene capable of encoding a soluble tumor necrosis factor receptor.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US94/02414

A. CLASSIFICATION OF SUBJECT MATTER

IPC(5) : Please See Extra Sheet.

US CL : 536/23.4; 514/44; 424/93B; 435/91.1, 172.3

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 536/23.4; 514/44; 424/93B; 435/91.1, 172.3

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

APS, Chemical Abstracts

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	US, A, 5,319,071 (DOWER ET AL) 07 June 1994, col. 27, line 30 to col. 34, line 17.	1-137
Y	UA, A, 5,180,182 (DOWER ET AL) 19 January 1993, col. 16, line 53 to col. 19, line 50.	1-137
Y	Pharmac. Ther., Vol. 29, issued 1985, M.J. Cline, "Perspectives for Gene Therapy: Inserting New Genetic Information into Mammalian Cells by Physical Techniques and Viral Vectors, pages 69-92, see entire document.	1-137

Further documents are listed in the continuation of Box C.

See patent family annex.

* Special categories of cited documents:

A document defining the general state of the art which is not considered to be of particular relevance

E earlier document published on or after the international filing date

L document which may throw doubt on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

O document referring to an oral disclosure, use, exhibition or other means

P document published prior to the international filing date but later than the priority date claimed

T

later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

X

document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

Y

document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

Z

document member of the same patent family

Date of the actual completion of the international search

10 JUNE 1994

Date of mailing of the international search report

JUN 23 1994

Name and mailing address of the ISA/US
Commissioner of Patents and Trademarks
